

# 2 The brain

## 2.1 Parts of the brain

Researchers study how the brain supports learning and memory. Each region has a role, and damage to one region changes behaviour in ways that can be measured in careful experiments over time.

Figure 2.1 shows the four lobes of the brain and where each one sits. The frontal lobe plans actions, while the occipital lobe processes what we see.

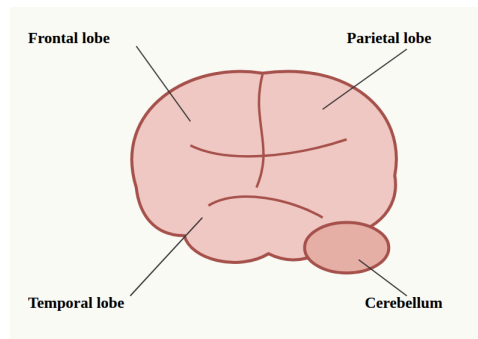

*Figure 2.1 The four lobes of the human brain*

Researchers study how the brain supports learning and memory. Each region has a role, and damage to one region changes behaviour in ways that can be measured in careful experiments over time.

## 2.2 The hippocampus

Researchers study how the brain supports learning and memory. Each region has a role, and damage to one region changes behaviour in ways that can be measured in careful experiments over time.

The hippocampus is a curved structure deep in the temporal lobe that is needed to form new long-term memories. As Figure 2.2 shows, it sits next to the amygdala.

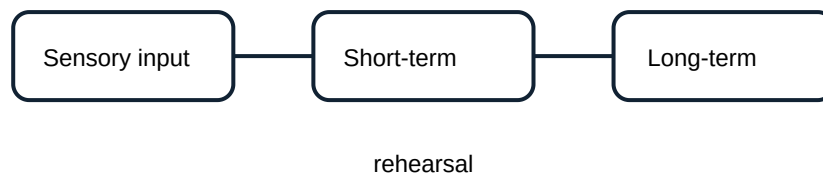

*Figure 2.2 The hippocampus and amygdala*

Researchers study how the brain supports learning and memory. Each region has a role, and damage to one region changes behaviour in ways that can be measured in careful experiments over time. Researchers study how the brain supports learning and memory. Each region has a role, and damage to one region changes behaviour in ways that can be measured in careful experiments over time.

## 2.3 The memory pathway

Researchers study how the brain supports learning and memory. Each region has a role, and damage to one region changes behaviour in ways that can be measured in careful experiments over time.

Figure 2.3 summarises the pathway from sensory input to long-term storage. Information that is rehearsed moves from short-term memory into long-term memory.
